The United States Department of Agriculture through the Specialty Crop Block Grant program of the Maryland Department of Agriculture The Maryland Grape Growers Association

#### INTRODUCTION

For many, the Chesapeake Bay defines the state of Maryland. There is keen interest in preserving and protecting the waters of the Bay and the fish, crabs, oysters, and other creatures that dwell there. Millions of dollars have been spent by local and state governments as well as the federal government to restore this amazing resource and to protect it for future generations.

Maryland's farmers are major participants in these efforts. Wine grape growing is one of the fastest growing agricultural sectors in the state with new vineyards being planted each year. Vineyards can now be found in every county. Wine grape farmers are eager to do their part to "Save the Bay".

Several members of the Maryland Grape Growers Association expressed interest in applying sustainable viticulture practices to grape growing. Due to that interest, Dr. Timothy Martinson, Senior Extension Associate in Viticulture, Cornell University was asked to make a presentation at the Maryland Grape Growers Association sponsored wine/grape industry, Annual Conference and Seminars.

Dr. Martinson's presentation, **Sustainable Viticulture: Promotion and Practices** was enthusiastically received. Many members of MGGA requested that the Association provide more guidance in sustainable practices for their Maryland Vineyards.

Maryland Grape Grower Association leadership organized a group of members to pursue ways of promoting sustainable viticulture practices, especially for Maryland wine grape growers. It was decided that the best way to reach that goal was to adapt the **New York Guide to Sustainable Viticulture Practice** for use in Maryland.

A Specialty Crop Block Grant from the United States Department of Agriculture was applied for through the Maryland Department of Agriculture. That grant was awarded to the Maryland Growers Association.

Soon thereafter, members of the grant committee were struck with major health issues and other life changing challenges and were not able to proceed with the program. Upon becoming MGGA president, Bob White was able to reorganize the grant committee. Now after some setbacks and more time than anticipated, a workbook designed specifically for Maryland is now available, **A Sustainable Practices Workbook for Wine Grape Growing in Maryland.** 

The Maryland Grape Growers Association hopes that this workbook will provide information, and resources to aid Maryland's wine grape growers to farm in a sustainable manner. MGGA encourages all wine grape growers to make use of the information supplied here to become better stewards of our land and the Chesapeake Bay.

#### PREFACE

This workbook is intended to help producers meet the increasing environmental and social challenges facing the wine/grape industry. There is a growing awareness of the effects the actions of each of us has on the Chesapeake Bay. This natural resource is a living, "protein factory" that in many ways defines the state of Maryland. The general public is demanding that steps be taken to protect this treasure.

As the concept of sustainable agriculture has grown, the agricultural community has agreed that practices must be developed that are economically, environmentally, and socially sustainable.

This workbook is designed to allow wine grape growers to assess their vineyard's position regarding sustainability. To help producers improve practices, it is important that this workbook serve as a measurement, as well as an educational, tool. It is to aid the individual grower. Its purpose is not to compare one grower's practices with another.

As time goes on there will be new and evolving sustainable practices. It is important that growers keenly keep aware of these new developments and incorporate them into their vineyard practices and routines. As we become good stewards of our resources, we can be profitable today and leave a legacy for generations to come.

> BRUCE PERRYGO COORDINATOR MARYLAND GRAPE GROWERS ASSOCIATION

This workbook contains questions in 8 sections. The questions address issues or practices that are important to good vineyard management. Each question is followed by four (4) options ordered on a sustainable scale, with "1" being the most desired (i.e. most sustainable) option and "4" being the least. The questions are designed to help you evaluate all areas of your current management practices, with each chapter covering a different production area. A sample question is presented on page 7.

Questions are often followed by a short sidebar designed to further explain the rationale behind the promoted practices and provide additional resources related to the topics. When reading through the possible answer options, we recommend starting at option #4 and moving toward option #1, choosing the option that your current practice fully encompasses. If you find that your present practice comprises part, but not all, of an answer, choose the higher score. For instance, if you presently perform only two of the three practices necessary to assess yourself a score of "2" on a certain question, score yourself a "3" on that question. Your scores will provide a baseline from which to develop an action plan and assess improvement after implementation of your plan. It is important to note that this is not a test and there are no "wrong" answers. Simply choose the answer that best describes what you do. In answering the questions, it may be helpful to think of a particular vineyard block rather than a range of different blocks and varieties. We recognize that different varieties may require different management approaches.

Some of the questions in the workbook may not be applicable to your farm, so you can skip the questions that do not apply to you and mark "NA" on the score sheet. Canopy management questions applicable to *vinifera* grapes, for example, will not be applicable to Concord production. Similarly, if you do not use irrigation, you can skip the irrigation section.

**ACTION PLAN.** Once you have completed the workbook, the next step is to develop an action plan based on the results of your self-assessment that will address the practices that you believe you can effectively modify within the financial and management capacity of your farm. Concentrate on the issues where you scored three or four, with the goal of modifying your practices to reach the more sustainable one or two rating. The action plan is yours, and only you will know what is practical and possible on your farm.

Please note that this workbook is not a production guide. Managing vineyards is a complex enterprise involving numerous site and variety-specific practices and weather conditions, along with skill and experience in making decisions. Not all questions will apply to your vineyard, nor are the options listed for management the only possible solutions. You are the person most familiar with your site and most suited to deciding what is applicable to your situation.

## NITROGEN (N) MANAGEMENT PRACTICES

|                            | <b></b>                 |                         |                          |                       |           |

|                            | the N applied           |                         | and veraison.            |                       |           |
|                            | prebloom and the        |                         |                          |                       |           |
|                            | remainder applied       |                         |                          |                       |           |
|                            | postbloom.              |                         |                          |                       |           |
|                            |                         |                         |                          |                       |           |

There is little absorption of N by roots prior to budbreak. The soil is cold and roots are inactive. Early vine growth depends almost entirely on N stored in the woody parts of the vine. It is unclear whether pre-budbreak application release organic fertilizers confers an advantage in terms of N availability to the plant.

#### Example:

Our grower applies nitrogen in the spring in one application about 1 ½ weeks before bloom. Based on this practice, the grower selects "2". Self-assessment scores can be recorded in the "YOUR RANK" column following each question and/or on the Workbook Scoresheet included with this workbook. In deciding whether or not to modify current

practice to reach the "1" level, the grower will have to consider whether the benefits (e.g. increased efficiency in timing and rates of nitrogen fertilizer application and the associated potential savings) outweigh the drawbacks (e.g. increased labor, tractor use and other potential costs).

#### I. SOIL MANAGEMENT

Vineyard sites in Maryland vary in slope, soil texture, depth, parent materials, pH, and elevation. There are three main geomorphic regions in the state, each with its own types of soils and climates.

**The Coastal Plain** is the area that surrounds the Chesapeake from the Atlantic Ocean to the Potomac River and the Fall Line. On the Eastern Shore the land is nearly flat. The Western Shore tends to be somewhat higher with small, rolling hills. Streams meander and are slow moving. Soils in this area are made up of Gravel, Sand, Silt, and Clay.

<u>The Piedmont Region</u> lies to the west and north of the Coastal Plain and extends west to the Blue Ridge. The diverse topography of the region includes rolling hills, plateaus, and ridges. There are narrow valleys with swift, rapidly moving streams. Soils contain schist, gneiss, metabasalt, and phyllite.

**The Appalachian Region** runs from the Blue Ridge, west to the state's borders. There are mountains and broad plateaus. In the far west, there are mountain ridges nearing 3,000 feet in elevation. Streams run in steep walled, narrow valleys. Much of the region is dominated by limestone, sandstone, shale, and siltstone.

Hillside vineyards are subject to erosion and runoff. Surface runoff carries sediment, nutrients, and pesticides into ponds and streams. Eventually, these make their way into the Chesapeake Bay causing serious degradation to Bay waters, as well as, to the animal and plant life that inhabit it.

Careful management of soils, starting before vines are planted and continuing through the life of the vineyard, is crucial for maintaining vineyard productivity and minimizing runoff of nutrients and pesticides. Questions in this section address runoff and leaching potential, pre-plant vineyard design, soil amendments, soil compaction, soil erosion, the use of cover crops and mulch to manage erosion, and water use in your vineyard.<sup>1</sup>

## SITE CHARACTERISTICS: DETERMINATION OF SOIL LEACHING AND RUNOFF POTENTIAL

## BACKGROUND

- 1. Compare the relative risk of ground and surface water contamination among different vineyard blocks on your farm.
- 2. Identify the vineyard blocks on which you may want to consider using more extensive water protection practices.
- 3. Set priorities for adopting vineyard floor management practices, constructing soil conservation structures, and making changes to nutrient or pesticide management practices.
- 4. Be applicable for both established vineyards and pre-plant situations.

Pages 10-13 will allow you to enumerate and classify the risk potential for each vineyard block. If the assessment shows a high or moderate risk of sedimentation or ground or surface water contamination, you will want to consider possible ways to modify that risk.

If you already know the leaching potential of your soil, you may want to skip to page 14.

## **VINEYARD SITE CHARACTERISTICS WORKSHEETS - INSTRUCTIONS**

- 1. If you know your vineyard's leaching and runoff potential, you may skip this section.
- 2. Use a County Soil Survey of your property to identify soils and slopes present on your land, or ask for assistance from your local Soil and Water Conservation District to obtain a computer-generated map of your property with soils and slopes identified.
- Identify major vineyard blocks or natural divisions with similar soils and slopes. Mark the location of each area on the map. Identify the predominant soil type and average slope in each area.
- 4. From the county soil survey, use information on each soil group to fill out the following table for each vineyard block. This will identify if a block has a high potential to leach pesticides or fertilizers into groundwater or a high potential for surface runoff that may carry fertilizers or pesticides into surface waters.

| Soil Hydrologic Group | DESCRIPTION  |
|-----------------------|--|
| _                     | Low runoff potential - high leaching potential.  |
| A                     | Mostly deep coarse-textured soils such as sandy loams, gravels, coarse gravelly loams. |
| 2                     | Moderately low runoff potential - moderately high leaching potential.                  |
| В                     | Mostly permeable loams.  |
| <b>a</b>              | Moderately high runoff potential - moderately low leaching potential.                  |
| C                     | Mostly fine-to-medium textured soils and/or those with imperfect drainage.             |
| <b></b>               | High runoff potential - low leaching potential.  |
| D                     | Mostly very fine-textured soils and/or those with poor drainage.                       |

#### **RATING OF RUNOFF/LEACHING POTENTIAL OF VINEYARD BLOCKS**

| Soil Hydrologic Group | RATING | <b>AVERAGE BLOCK SLOPE</b> | RATING |
|-----------------------|--------|----------------------------|--------|
| Α                     | 1      | < 3%                       | 1      |
| В                     | 2      | 3-6%                       | 2      |
| С                     | З      | 7-12%                      | З      |
| D                     | 4      | < 12%                      | 4      |

|   | Vineyard Block ID | Hydrologic Soil Group Rating | Average Block Slope Rating | Addition of Rating Numbers |
|---|-------------------|------------------------------|----------------------------|----------------------------|
| 1 |                   |                              |                            |                            |
| 2 |                   |                              |                            |                            |
| 3 |                   |                              |                            |                            |
| 4 |                   |                              |                            |                            |
| 5 |                   |                              |                            |                            |
| 6 |                   |                              |                            |                            |
|   |                   |                              |                            |                            |

#### Addition of Numbers - Results

2 – 3 = High Leaching Potential. Use caution when making ground-directed herbicide or fertilizer applications especially when heavy rainfall is expected.
 Split applications of nitrogen fertilizers are recommended.

4-5 = Intermediate Conditions. The site may be intermediate in both the risk of runoff and leaching potential. For example, a flat site on heavy clay would likely have less runoff and more leaching than a hillside vineyard.

Similarly, a well-drained, gravelly soil on steep slopes may be subject to both runoff and leaching.

6-8 = High Runoff Potential. Installation of filter strips around vineyards is highly recommended. Delay application of pre-emergence herbicides and fertilizers when >1" of rainfall is forecast.

## MANAGEMENT CONSIDERATIONS FOR SITES WITH HIGH LEACHING OR RUNOFF POTENTIAL

|                          | 1 - Low Risk                     | 2 | 3 | 4 - High Risk              | YOUR RANK |

#### http://go.umd.edu/SoilTissueNematodeTesting

High nematode populations have been found in some areas of former tobacco cultivation. The dagger nematode Xiphenema index has been found to vector ringspot viruses, a disease of concern for hybrid varieties. Consequently, assessing the soil nematode populations may help to address a later problem. One of the best defenses against nematode injury is excellent early care of the vineyard, as healthy vines are better able to tolerate an infestation than compromised vines.

For more information on nematodes, sampling, and biorenovation, go to: http://go.umd.edu/Biorenovation

The need for subsoiling should be judged based on local experience and/or the use of a penetrometer, a device that measures soil compaction. The need for subsoiling should be assessed in consultation with a vineyard consultant, University of Maryland Extension and/or Natural Resources Conservation Service. While preplant subsoiling is not a standard practice, it may be of help on sites with poor drainage.

|                       | planting.   |  |   |   |           |

Three major types of grapevines are grown in Maryland: natives, hybrids, and *V. vinifera* types. Native labrusca types are adapted to acid soils, with optimum pH around 5.5. *V. vinifera* grapevines are more adapted to neutral soil pH (6.5-7.0) and can exhibit nutrient deficiencies in acid soils. Interspecific hybrid varieties are hybrids of American (often acid-adapted) *Vitis* spp. and *V. vinifera*, so are thought to have an adaptation to intermediate soil pH (6.0) somewhere between the European and American parents. Although this idea has not been rigorously tested for every hybrid, these guidelines seem to work reasonably well in practice.

Application of lime should be done in the year prior to planting. Additions of large amounts of lime just before planting can induce manganese, potassium, or magnesium deficiencies in vines. Also, lime applied immediately preplant may not have time to react with soil particles.

| PREPLANT CONSIDERATIONS   |  |   |   |  |           |  |
|---|--|---|---|--|-----------|--|
|   | 1 - Low Risk   | 2   | 3   | 4 - High Risk  | YOUR RANK |  |
| For sites with low soil<br>organic matter (< 3%<br>for Coastal, < 2% for<br>Piedmont and<br>Appalachian regions),<br>is additional matter<br>added? | Organic matter is supplied<br>through one of the<br>following methods: Cover<br>crops (particularly with<br>sorghum/sudan hybrids);<br>Compost; or Manure,<br>preferably composted.            |   |   | Organic matter is not<br>added, particularly on<br>sandy sites.              |           |  |
| How are vineyard rows<br>oriented with respect<br>to slopes?  | Vineyard rows run<br>perpendicular to the slope<br>(across slope).<br><b>OR</b><br>Slope <u>along rows</u> is < 3%;<br>hill slope is < 12%.<br><b>AND</b><br>Direction of slope is<br>uniform. | Vineyard rows run<br>perpendicular to the<br>slope.<br><b>AND</b><br>Slope <u>along rows</u> is < 6%;<br>hill slope is < 12%.<br><b>AND</b><br>Some side slopes<br>present. | Vineyard rows are<br>perpendicular to the<br>main slope.<br><b>AND</b><br>Substantial side slopes<br>are present (slope<br>direction is not uniform). | Vineyard rows run up<br>and down the slope.<br><b>AND</b><br>Slopes are >6%. |           |  |

Vineyard rows can reduce the effective slope by channeling water across it. Such protection is less effective when the slope *along vineyard rows* exceeds 3%, when slope direction is not uniform (side hills present), or when the main slope exceeds 12%.

| How is soil<br>compaction<br>addressed, if<br>evident? | Equipment is chosen or modified<br>to minimize compaction (e.g.<br>lightest equipment possible,<br>wider or larger diameter tires,<br>tire pressure is as low as<br>possible).<br>AND<br>In compacted areas, subsoiling is<br>completed every other year in | In compacted areas,<br>subsoiling is completed<br>every 2 to 3 years.<br><b>AND</b><br>Equipment use is usually<br>avoided when soils are<br>saturated. | Compaction status is<br>not known.<br><b>AND</b><br>Equipment is<br>sometimes used when<br>soil is saturated. | Compaction status is<br>not known.<br><b>AND</b><br>Equipment is<br>regularly used when<br>soil is saturated. |           |  |  |
|  | the tire tracks, or deep-rooting<br>cover crops are planted to help<br>restore soil structure.<br><b>AND</b><br>Equipment use is avoided when<br>soils are saturated.   |   |   |   |           |  |  |

Common implements used for subsoiling include the chisel plow, spader, and paratill. A chisel plow typically has two shanks that ride in the tire tracks. It is more effective with drier soil and can extend to a depth of 18". The spader, a series of rotary shovels, loosens topsoil and fractures subsoil. It reportedly works in both dry and wet soils to a depth of about 14". The advantage to a spader is that it incorporates green cover. The paratill consists of a pair of coulters that slice the soil followed by 2 angled legs, each with a foot and riser plate on the bottom. It typically reaches depths of 12-18". It lifts and partially shatters the soil profile with maximum shatter occurring with drier soils. It does not mix top and subsoils, nor create clods, or large trenches. Note that it is not unusual for the chisel plow and paratill to sever vine roots in established vineyards.

|                           |                           |                           |                            |                          |           |  |  |

Cultivation, whether in the row middle or under the trellis, can have negative consequences particularly if done in excess. It renders soils more prone to erosion, destroys soil organic matter and can alter the quantity and diversity of soil microbial populations. Row middle tillage can, and should, be done to periodically renovate row middles (reduces weed populations such as dandelions) and as a vine management tool in dry years (reduces competition for water).

Application of straw mulch to row middles is a highly beneficial practice, particularly on eroded hillside vineyards. It conserves moisture, adds organic matter to the soil, and is highly effective in reducing erosion and runoff. It is commonly applied to alternate row middles, and often applied in the fall after harvest. Straw mulch can supply significant amounts of potassium to soils. It is most cost effective to use when growers bale the straw themselves and have open land that they can devote to producing it. Round bales are most often rolled out using self-fabricated tractor-mounted equipment to unroll the bales.

## **ESTIMATING AVAILABLE NITROGEN SUPPLIED BY COVER CROPS**

To estimate the amount of nitrogen in your cover crop, you must assess the total yield of the cover crop and the percentage of nitrogen in the plants just before they die.

There are two ways to estimate yield. The most accurate way is to take cuttings from several places (of known surface area) in the vineyard, then dry, and weigh them. Clip the plants at ground level within the known area. Dry them out in the sun for a few days and use the following formula to determine the per acre yield of dry matter.

# Yield (lbs/acre) = $\underline{\text{Total wt of dried samples (lbs)}}{\text{ft}^2 \text{ sampled}}$ x $\underline{43,560 \text{ ft}^2}{\text{1 acre}}$

An easier but less accurate method is to estimate your yield from the height of the cover crop and its percent cover. At 100% cover and 6" height, most grass legume cover crops will contain roughly 2000 lbs/acre of dry matter. For each additional inch, add 150 lbs. For example, a typical fescue, perennial ryegrass, or white clover vineyard cover crop that is 8" tall will yield 2000 lbs/acre of dry matter plus an additional 150 lbs for each additional inch for a total of 2300 lbs of dry matter per acre. If the strand is less than 100 percent, multiply by the percent cover. In this example, for an 80% cover you would obtain: 2300 lbs x 0.80 = 1840 lbs dry matter/acre.

To convert the yield to total nitrogen, use the following guideline: cover crop grass legume mixtures contain 2-3% N before flowering

and 1.5-2.5% after flowering. Therefore, total nitrogen in the cover crop = yield (lbs/acre) x % N/100.

To estimate the nitrogen available to the vines, divide the total nitrogen by 4 for cover crop material left on the surface in a no-till system.

So, in our example, if you mowed the vineyard three (3) times during the season when the cover reached a 6" height you would have 6000 lbs/acre of dry matter.

#### Total nitrogen = 2000 lbs/acre x 3 cuttings = 6000 lbs

#### 6000 lbs/acre x 2.5\* = 150 lbs

100

\*Average nitrogen percentage before flowering.

Nitrogen available to vines =  $\frac{150 \text{ lbs}}{4}$  = 37.5 lbs/acre

This procedure provides a gross estimate of available nitrogen in the soil from cover crops. To obtain a more accurate estimate you would have to send plant samples to a lab for analysis.

Organic matter decomposition in the soil also produces nitrogen. Each 1% of organic matter supplies 15-20 lbs/acre/year of nitrogen (Dr. Terry Bates, Cornell University, Fredonia Vineyard Laboratory).

Modified from: Sustainable Agriculture Network (1998).

### THE BENEFITS OF USING COVER CROPS IN VINEYARDS

Cover crops do not need to be worked into the soil. Cultivation, whether in the row middle or under the trellis, can have negative consequences, particularly if done in excess. It renders soils more prone to erosion, burns off soil organic matter, and can alter the quantity and diversity of soil microbial populations. Row middle tillage generally negates the benefits of a row middle crop (no net increase in organic matter as it burned off roughly as fast as it is added). However, row middle tillage can and should be done to periodically renovate row middles (reduces weed populations such as dandelions) and as a vine management tool in dry years (reduces competition for water). In regard to mowing, more organic matter is preserved by mowing and letting the residue lie on the surface versus cultivation of any kind (roots contribute to organic matter as well).

From Ohmart and Matthiasson (2000):

- Permanent cover crops are the most practical and cost effective means of supplying the organic matter needed to maintain and improve the soil.
- Cultivation decreases organic matter.
- As the cover crop decays, it provides nutrients for the grapevines.
- Grass cover crops usually require some added nitrogen (20-40 lbs per acre), whereas legumes may require phosphorus and sulfur and should not receive any nitrogen, otherwise they become weedy.
- Different types of cover crops can either reduce or enhance vine growth.
- Cover crops tend to use more water than clean cultivation. Increased infiltration of rainfall may offset this loss in some years.

Compost is<br>not analyzed.<br>AND | <b>BUT</b><br>Vine prunings are<br>chopped and remain<br>in vineyard.* | AND<br>Vine prunings are<br>removed from<br>vineyard.* |           |
|   | well as contaminants.<br>AND<br>Vine prunings are chopped<br>and remain in vineyard.*   | Vine prunings are<br>chopped and remain in<br>vineyard.*  |  |  |           |

It is most practical to apply compost to a swath under the trellis rather than a broadcast application. Reasons include limited availability of high quality compost, the fact that large quantities are needed, and the expense involved. Dr. Ian Merwin, of Cornell University's Department of Horticulture, has documented that compost application increases soil microbial activity (CO<sub>2</sub> evolution), CEC (Cation Exchange Capacity), and available P, Ca, and K. Compost application can also result in shifts in microbial community structure. Caution – Compost/organic matter may add desirable components to the soil, however excessive application may lead to long term increases in vine vigor (especially for *vinifera*) which may have deleterious effect on fruit quality.

\*Chopping the prunings may aid movement through the vineyard rows, removal of vine prunings may be warranted to reduce fungal disease infestations.

## CALCULATING COMPOST APPLICATION ON VINE ROWS

#### **Examples**

Row spacing: 7 ft between rows x 5 ft between vines in row
Rows: 350 ft long; approximately 18 rows per acre
Compost: Have available approximately 5 tons/acre of compost 10,000 lbs/18 rows = 550 lbs/row

To apply compost to a certain depth: There are 1.5-2 yd<sup>3</sup>/ton 350 ft row x 2 ft swath x 0.042 ft (0.5" deep layer of compost) = 29 ft<sup>3</sup> per row x 18 rows/acre = 522 ft<sup>3</sup> 522 ft<sup>3</sup>/27 ft<sup>3</sup> per yd<sup>3</sup> = 14 yd<sup>3</sup>

<u>Summary</u>: The amount of compost needed to apply a 2 ft swath under the trellis 0.5" deep over 1 acre of vines is 14 yd<sup>3</sup> or between 7 and 9 tons of compost. Generally, compost applications should be limited to no more than 10 tons/acre annually to avoid nutrient imbalances.

## BENEFITS OF SOIL ORGANIC MATTER

- Attracts and holds nutrients in an available state, reducing leaching losses.
- Increases soil water-holding capacity.
- Binds soil particles into crumbs (aggregates), producing a granular structure that promotes the penetration of air to roots, the capillary movement of water and the penetration of roots through the soil.
- Transforms into vitamins, hormones, and other substances, which stimulate growth in plants.
- Feeds soil organisms, which in turn feed soil predators that also prey on root pests.

The soil builds up organic matter faster if the organic material is left on the surface than it does if it is worked into the soil. The oxygen introduced by the tillage "burns off" the organic matter. The natural process is for the material to "melt" into the soil over time.

From Ohmart and Matthiasson (2000)

|-------------------------|---|---|--|---|-----------|--|--|--|
|                         | 1 - Low Risk  | 2   | 3  | 4 - High Risk                                 | YOUR RANK |  |  |  |
| How is pomace utilized? | Pomace is composted on<br>site and returned to the<br>vineyard. | Pomace is composted off<br>the farm and returned to<br>the vineyard as mature<br>compost. | Pomace is spread in the vineyard, fresh. | Pomace is not<br>returned to the<br>vineyard. |           |  |  |  |

Recycling of organic matter back into the vineyard is important to maintain soil organic matter and soil biodiversity. Pomace can be combined with a carbon source - leaves, for example - to create a more nutritionally balanced product that enhances the soil over and above the addition of fresh pomace. Though difficult to totally eliminate, even through proper composting, grapevine seedlings will proliferate from the spreading of fresh pomace. These seedlings are often infected by downy mildew, but are generally controlled through standard weed control practices such as herbicide use, cultivation, or mowing. Caution – Pomace contains large amounts of K which may have undesirable effect on fruit pH. If your vines and soil have high to excess K, do not return pomace to the vineyard.

## **II. NUTRITION MANAGEMENT**

Nutrient management is important to ensure healthy, productive vineyards. It is not only important to have sufficient amounts of each nutrient available to the vine, but also to establish an appropriate balance of the relative amounts of all nutrients. Nutrient excess or deficiency can affect both yield and fruit quality, both for bulk wine and juice grape varieties and premium wine varieties. Nutrient availability is affected by soil texture, moisture, pH, and many other factors. It is important to adapt vine nutrition practices to site-specific vineyard conditions, rather than applying a "one-size-fits-all" approach to all vineyard blocks.

The Maryland Department of Agriculture requires all farms with >\$2500 annual income to have a Nutrient management plan produced by a certified advisor. See

http://mda.maryland.gov/resource\_conservation/pages/nutrient\_ma nagement.aspx or contact your local UME County Extension Educator or Specialist for more details.

For more details on the UME Nutrient Management Program visit: http://www.extension.umd.edu/anmp

Creating and utilizing an approved Nutrient Management Plan for your vineyard will assure that you are in legal compliance and offer optimal and economical management of nutrients for your vineyard.

Excess fertilizers – notably nitrogen and phosphorus – can also contaminate ground and surface waters. Managing nitrogen fertilization is most important because nitrogen is the most common fertilizer applied to vineyards, it directly affects vine size and quality, and it moves readily through the soil. Phosphorus can trigger excessive growth of organisms in surface water, leading to algal blooms and depletion of oxygen. Grape growers rarely add phosphorus to mature vineyards, except indirectly through

application of phosphorus-rich manures, so excess phosphorus is not a common concern.

This section addresses the uses of soil and tissue samples to guide nutrient management decisions and special consideration for using soil characteristics and vine growth as guides for nitrogen management.

Nitrogen is the plant nutrient most susceptible to loss by leaching (movement through soil) into groundwater. Specific health problems are associated with nitrate contamination of drinking water supplies. Nitrate levels higher than 10 mg/l (designated the Maximum Contaminant Level by the US EPA) have been found in groundwater, often in association with spring runoff or heavy rainfall events. It is therefore absolutely essential for grape growers to use nitrogen in a thoughtful and sparing manner.

#### Key Points for N Fertilization:

- If winter injury has occurred, delay N decisions until after fruit set to allow evaluation of vigor level and fruit set.
- N deficiency symptoms: pale green leaves, small leaves, spindly shoots, short internodes, poor fruit set.
- N excess symptoms: dark green, "dinner plate" leaves, bullwood, succulent shoots with long internodes, poor fruit set.
- Vinifera grapes do not require N fertilization in most years. Refer to your Nutrient Management Plan for details.

For more information on Nitrogen nutrition, go to: http://go.umd.edu/TVitNFertilization

| Is contribution of<br>Nitrogen (N) from<br>organic sources<br>considered?                                 | N contributions from<br>compost, legumes, mulch,<br>and cover crop residues<br>are estimated to reduce N<br>fertilizer rates.  |  |   | N contributions from<br>organic sources are not<br>used to reduce N<br>fertilizer rates.   |           |  |  |  |

Nitrogen release from organic matter such as compost and mulch can be calculated from their analysis (if known) and the Carbon to Nitrogen, C:N, ratio. According to Dr. Terry Bates (Cornell University, Fredonia Vineyard Lab), if the N content of the organic matter is >2.5% or the C:N ratio is < 20, N will be released. Materials with a C:N ratio >20 require further decomposition before they can release N, and in fact may lead to N deficiencies as N is sequestered by soil microorganisms.

| NITROGEN (N) MANAGEMENT PRACTICES   |   |  |                                      |  |           |  |  |  |

| Are organic fertilizers<br>used?  | All fertilizers, foliar and ground applied, are organically acceptable.   | A portion of fertilizers used is organically acceptable.   | Only synthetic fertilizers are used. |  |           |  |  |  |

While organic fertilizers offer potential benefits that synthetic fertilizers may not, increased costs may preclude their use, particularly in bulk production vineyards.

Organic fertilizers are slower to release N, often have an unpredictable rate of release and are more dilute. Some sources report that organic fertilizers can also be high in salts and warn against over-application. On the other hand, if used long-term, they may improve the quantity and quality of soil organic matter, promote soil biodiversity and reduce leaching (through the improved organic matter and slow release of N). Misapplication of any fertilizer – organic or synthetic – can pose a leaching hazard, not to mention a potential headache in the vineyard.

It is more difficult to ascertain the exact rate of organic fertilizer to add given the unpredictable rate of N release. Use of split applications and supplementation with foliar N will allow tweaking of the N rate. Examples of common organic N fertilizers include peanut meal, soybean meal, feather meal, and fish meal.

| In irrigated vineyards,<br>how is N fertilizer<br>applied? | If drip irrigation is installed,<br>fertigation is used to<br>efficiently apply small doses<br>of N to vines.   | A combination of<br>fertigation and ground<br>applied N is used. |  | Only ground or foliar<br>applied N is used.                  |           |  |  |  |
| If foliar N is used, when<br>is it applied?                | Foliar N is used only when<br>necessary or not at all. Use<br>is based on visual cues from<br>vines and/or tissue analyses<br>reporting < 1.0% N in spring. |  | Foliar N is used several<br>times, its use based on<br>the calendar. | Foliar N is included in<br>most tank mixes<br>automatically. |           |  |  |  |

Early season foliar N is common in winegrape vineyards and may benefit N deficient vineyards. However, N needs are best addressed through addition of organic matter and/or ground application of N fertilizers.

Clusters have a fairly high N demand around veraison. Foliar-applied urea (or other foliar feeds containing N) applied several times around veraison can increase yeast-assimilable nitrogen (YAN) in musts, particularly when drought has limited N uptake from the soil. In Cornell trials over the last few years, up to 10 lbs urea in 100 gallons (5 lbs actual N) has been used without burning the foliage. This is not a panacea for eliminating Atypical Aging (ATA, a wine defect associated with limited N uptake in drought years in white wines), but has had a secondary role (the more major effect occurring with irrigation) in reducing ATA. It is effective in bumping up the YAN values, which may help winemakers avoid stuck fermentations. It does not appear to prolong or "restart" shoot growth, nor delay wood maturation.

## MACRONUTRIENT MANAGEMENT PRACTICES: CALCIUM (CA), MAGNESIUM (MG), POTASSIUM (K)

The application of Ca, Mg, and K as foliar nutrients is not well understood. Use can be based in part on soil/tissue analysis and visual clues. Magnesium deficiency is often addressed through the use of foliar applied Epsom salts. In general, due to the relatively large quantities required by vines, macronutrient nutrition is best addressed through the root system. Potassium is a very critical nutrient in the vineyard and very plentiful in Maryland soils. Excess K can lead to problems with elevated fruit pH during harvest, so applications, if any, should be very judicious. This will be reflected in your Nutrient Management Plan.

Excessive amounts of P in surface water promote the growth of algae and other aquatic organisms, potentially depleting oxygen levels in surrounding water bodies. This can have profound impacts on aquatic life. Because P is less available in acid soils, simply increasing soil pH to 6.0-6.5 will increase P availability. Generally, P fertilization has not been found to benefit vineyards in part due to the immobility of the nutrient.

|                            |                         |                          |                         |                      |           |

Some soil labs provide percent base saturation (% BS), the relative percentage of the cations Ca, Mg, K, Na (sodium) and H (hydrogen) occupying exchange sites on soil particles. The following standards are used: Ca, 65-75%; Mg, 10-15%; K, 3-5%; Na, < 2% (more important for CA growers where high sodium soils can be a problem); and H, depends on pH. BS percentages are useful in choosing a type of lime or fertilizer (e.g. use of high Mg [dolomitic] lime vs. high Ca lime).

|                        |   |   |                         |                           |           |

There are many types of micronutrient fertilizers. The most commonly applied are boron, manganese, and zinc. Because these elements are required in small quantities and petiole analyses sometimes do not reflect a deficiency (due to time of sampling, type of tissue sampled, dilution effects due to vigorous growth, etc.), it is sometimes necessary to use these fertilizers based on historical knowledge of the vineyard. It is often hard to gauge efficacy of micronutrient fertilizers as they are used in small quantities and the elements are involved in specific enzyme systems and chemical pathways. If possible, leave a section of the vineyard untreated. To judge potential benefits, evaluate subsequent fruit quality and quantity. Examine soil and petiole analyses. Extra diligence in necessary in Maryland's coastal plain (sandy) soils as B is typically low and B added to the soil is prone to leaching, especially when organic matter is low. Pre-bloom foliar sprays are most efficient.

#### III. VINEYARD MANAGEMENT

In the humid Mid-Atlantic, vineyard management is closely linked to the dual goals of pest management and production of quality fruit. With major challenges inherent in warm climate viticulture, vineyard management practices must be fine-tuned to achieve goals. From vine spacing and training system choices to pruning practices, canopy management practices and winter protection methods, vineyard cultural practices affect profitability and fruit quality, and need to be applied in a flexible manner to confront each season's unique and different challenges. One overall goal is to strike a balance between cropping levels and vegetative growth to ensure achievement of optimum yield of mature, high quality fruit.

This section addresses variety, rootstock, and vine spacing choices, timing and application of winter injury protection, adjustment of cropping levels and shoot density, timely application of canopy management practices, and crop estimation as components that influence environmental sustainability and profitability.

|                       |                           |                           |                      |  |

On replant sites, hybrid varieties susceptible to tomato ringspot virus should be grafted onto resistant rootstock. This includes varieties such as Vidal blanc, Baco noir, and DeChaunac.

| PLANT MATERIAL AND PLANTING   |   |   |   |  |           |  |  |
|---|---|---|---|--|-----------|--|--|
|   | 1 - Low Risk  | 2   | 3   | 4 - High Risk  | YOUR RANK |  |  |
| Is fungal resistance<br>considered when<br>selecting varieties<br>for planting? |   | Fungal resistance is<br>considered and<br>varieties resistant to<br>most fungal diseases<br>are selected. | Fungal resistance is<br>considered and<br>varieties moderately<br>resistant to some<br>fungal diseases are<br>selected. | Vinifera varieties that<br>are highly susceptible<br>to fungal diseases are<br>selected. |           |  |  |
| Is the row<br>orientation<br>appropriate for the<br>site?                       | Rows are oriented N-S to maximize<br>sunlight interception. Where<br>necessary, rows are perpendicular to<br>slopes to minimize erosion.  |   |   | Row orientation is not<br>appropriate for the<br>site and<br>variety/rootstock.          |           |  |  |
| Does a map of the<br>vineyard exist?  | A detailed map exists of the vineyard,<br>allowing accurate calculation of<br>acreage. The map includes varieties,<br>drainage tiles, irrigation<br>mains/submains, buildings, roads,<br>areas of runoff, water bodies (lakes,<br>ponds, streams) and wells. Map<br>information is tied to production<br>records. |   | A map exists but is<br>inaccurate or<br>incomplete.   | No map exists.   |           |  |  |

Matching the variety to the site, is especially important because of the distinct, diverse regions of Maryland. The University of Maryland Extension has researched many variety /location combinations around the state and has very site specific recommendations; contact your local County Extension Educator or State Extension Specialist for details.

It is generally recommended that all hybrids be grafted, especially Chambourcin, Vidal Blanc, Chardonel, Seyval Blanc and Traminette. On replant sites, hybrid varieties susceptible to tomato ringspot virus should be grafted onto resistant rootstock. This includes varieties such as Vidal Blanc, Baco Noir, and DeChaunac.

|---|---|--|---|--------------------------------------|-----------|
| Are there any on-farm<br>experiments evaluating<br>plant material or<br>trellising options? | Experimental varieties,<br>rootstocks, and/or training<br>systems are being<br>evaluated on a small scale.<br>Data is taken to evaluate<br>performance. | Experimental varieties,<br>rootstocks, and/or training<br>systems are being<br>evaluated on a small scale.<br>Evaluation is anecdotal,<br>data is not taken. |   | No experimentation<br>is being done. |           |

On-farm experimentation can encompass almost anything from informal evaluations to formal, replicated field trials. Key ingredients that must be used to make field comparisons useful are: **1**) vary only one practice at a time; **2**) leave a portion of the same vineyard block "untreated" or with your standard practice; **3**) measure something objective; and **4**) record your observations. Area extension programs may be useful in helping growers design informal or formal trials. Here are a couple of publications that may be useful for setting up on-farm trials:

How to Conduct Research on your Farm. Northeast Sustainable Agriculture Research and Education Program (SARE) http://www.sare.org/publications/research/research.pdf

| Is vine size monitored?  | Prior to pruning each<br>vineyard block, randomly-<br>selected, permanently-<br>tagged vines are pruned and<br>the brush is weighed.   | Prior to pruning each<br>vineyard block, a few<br>representative vines per<br>acre are pruned and the<br>brush is weighed.  | Though vine size is<br>monitored, averages<br>exist on a whole farm<br>basis rather than block<br>by block.                          | No attempt is made<br>to monitor vine size<br>or track pruning<br>weights.                              |  |
| One of the key measures<br>facilitate the production<br>addressed in many texts  | of vineyard performance is vir<br>of economical yields of high qu<br>including the classic work, Sun   | ne size. Vines must be bala<br>uality fruit, whether dealing<br><i>light Into Wine</i> , by Smart ar  | nced to facilitate light a<br>g with labrusca, hybrid, o<br>nd Robinson (1991).  | nd air penetration. The<br>or vinifera vines. This to   | ey must also<br>opic is                  |

Vine size assessment is done primarily through the weighing of dormant vine prunings. Typically, the weight of canes on a per vine basis ranges from 0.2 – 0.4 lbs pruning weight/ft of row. The ideal weight is related to variety, yield goals, inherent vigor of the scion, etc. For labrusca and hybrid varieties grown on divided canopies, pruning weights would reflect the doubling of linear feet of canopy.

Labrusca and bulk hybrids: Yield is determined by crop estimation at 30 days post-bloom. Crop reduction takes place at that time, if necessary. For every 3 days the bloom date is earlier or later than the long-term average, an additional ton of fruit can be ripened (when it is early) or must be removed (when it is late).

Vinifera and premium hybrids: Yields are adjusted according to the parameters above. In cooler seasons/vintages, some crop reduction may be necessary to ripen late season red varieties such as Cabernet Sauvignon.

| Is yield estimated<br>properly? | Yield estimation is based<br>on historical average<br>cluster weights and mid-<br>season sampling of<br>clusters. | Yield estimation is based<br>on cluster counts and<br>historical average cluster<br>weights. | Yields are estimated by<br>looking at the vines and<br>guessing or counting<br>clusters on a few vines. | Yields are not<br>estimated. |           |

Vinifera: The most accurate system for predicting yields is based on cluster weights during "lag phase" which is the period when the growth of berries slows temporarily (typically about 55 days after first bloom). The other traditional method is based on a running historical record of cluster weights for that variety block.

For more detailed information on crop estimation, go to : http://go.umd.edu/TVitCropEstimation

## MAINTAINING VINEYARD PROFITABILITY

|                     | 1 - Low Risk  | 2  | 3   | 4 - High Risk         | YOUR RANK |
|---------------------|---|--|---|-----------------------|-----------|

| counted and         | and replaced every year. For                                    | every other year; where  | replaced every few                                  | replaced sporadically |           |
| replaced regularly? | non-grafted vines, layering is<br>done to replace vines.<br>AND | appropriate, layering is<br>practiced every other year.<br>AND | years; layering is<br>practiced every few<br>years. | or not at all.        |           |
|                     | Yield records are adjusted to account for missing vines.        | Yield records are adjusted to account for missing vines.       |   |                       |           |

Missing vines reduce vineyard profitability and lead to inefficiency in use of pesticides and fertilizers. Yield must be estimated with missing vines taken into consideration. If overall yield is 4 tons/acre but 50% of vines are missing, functional crop is therefore 8 tons/acre, a potential overcrop.

|                    |                              |                               |                        |                        |
|                    |                              |                               |                        |                        |

Many growers in MD have a wide range of varieties with different prices and inputs. Knowing what is spent in each individual block is crucial for making vineyard management decisions and improving profitability. This is particularly true for natives and bulk hybrids. For more detailed information and tools on keeping records to evaluate vineyard profitability, go to : http://go.umd.edu/VineyardEconomics

#### **IV. IRRIGATION MANAGEMENT**

Irrigation can be an important management tool for managing vine water relations, particularly in areas with sandy or gravelly soils, young vineyards with limited root systems, and soils with limited water-holding capacity. The availability of water to the vine (both in amount and timing) plays a crucial role in fruit quality. Drought stress limits yield and reduces the vine's ability to fully ripen the fruit, while surplus water can lead to excessive vine growth, loss of fruit quality, and delayed or reduced winter acclimation. Rainfall generally meets or exceeds vine needs in the Mid-Atlantic.

Irrigation also presents the opportunity to deliver fertilizers efficiently to vines through fertigation. The benefits include better timing and placement of fertilizer in the root zone, minimization of losses to volatilization and leaching, and reduced costs associated with field application of fertilizers.

Efficient use of irrigation involves proper maintenance and design of irrigation systems and an understanding of how to apply the right amount of water at the right time to benefit vines. Questions in this section address design, maintenance, and efficient operation of irrigation systems for vineyards.

Tensiometers reveal soil moisture potential in a specific area. They read changes in soil moisture by measuring the vacuum created by water movement through a ceramic tip. This mimics how soil moisture moves into the root zone of a plant. Tensiometers can help determine when to irrigate but not how much water should be applied. Begin irrigation when the tensiometer reads between 30 and 40 centibars. Observe the response on the tensiometer after irrigating. If it shows that the soil is wet (a gauge reading of 0-10), the system is working well. Operation times can be adjusted based upon the response of the tensiometer.

There are a number of other methods for measuring soil moisture such as neutron probes and gypsum blocks. Alternatively, a more accurate method may be to measure vine water potential using pressure bombs.

#### SUSTAINABLE VITICULTURE • IRRIGATION MANAGEMENT

Vine water demand is highest as leaf area increases in spring and summer. Similarly, large canopies such as divided or minimally pruned canopies have higher water requirements than smaller canopies such as those in VSP training. According to Dr. Alan Lakso, a Concord vine with a full canopy needs about 4 - 4.5 gal/day in July and August. It is likely that vinifera vines with smaller canopies require less water.

Once the application rate of the system has been determined, (see previous sidebar) operating time can be determined. This is the length of time necessary to replace the water a single vine uses per day. Assuming a peak consumptive use for vinifera grapes is between 0.2 and 0.25 inches per day, calculation of irrigation time is possible by estimating the rooting area of the vine in square feet. For example: Vines are planted 4' x 8', estimated rooting area is 32 ft<sup>2</sup> and estimated peak consumptive use is 0.23 in/day.

 $0.23 \text{ in/day}/12 \text{ in/ft } x 32 \text{ ft}^2 x 7.48 \text{ gal/ft}^3 = 4.59 \text{ gal/vine/day}$ 

<u>4.59 gal/vine/day</u> = \_\_\_\_hrs of operation # emitters/vine x gal/hr/emitter To minimize leaching, do not exceed calculated operation time for peak consumptive use.

Peak consumptive use (PCU): Weather data was collected from a weather station located on a LI (Long Island) sod farm. The data was entered into an irrigation-scheduling model (Blaney Criddle Method) from Michigan State to calculate consumptive use for specific crops. PCU is the average daily amount of water consumed in evaporation from the soil and transpiration through the leaves in the photosynthetic process by a crop during the 6 - 10 days of the highest water consumption of the season. It generally occurs as the crop is nearing harvest, when vegetation is most abundant and temperatures are high.

#### V. WEED MANAGEMENT

Weed management is more properly termed "vineyard floor management", as distinct management strategies are implemented for the region under the trellis and the row middles. Vegetation under the trellis must be managed to minimize competition with vines from the key bloom-to-veraison growth stage, after which weed growth has less impact on vine function. Studies have shown that crop losses due to poor weed management are higher than losses due to diseases and insects combined. Row middles can be managed to influence both nitrogen and soil water availability and hence vine vigor. While frequent rainfall often promotes growth of weeds, it also permits establishment of cover crops that can help growers manage water use to limit excess vigor.

This section emphasizes that integration of mechanical and cultural practices with judicious choice and usage of herbicides to achieve a grower's management objectives. Proper choice and timing of preemergence and post-emergence herbicides, consideration of tillage, and other non-chemical control methods, proper care and calibration of weed sprayers, and use of cover crops and mulches in row middles where appropriate are covered in this section, along with critical vine development stages (bloom-to-veraison) for reducing weed competition under the trellis.

Photography credits: Bruce Perrygo and Tim Stephens, MGGA members

As part of environmentally responsible vineyard management, it is not necessary to have pristine weed control throughout the season. The most critical time for weed control is budbreak through veraison, after which some additional weed growth is not viticulturally harmful. However, weeds should not interfere with harvest activities, contaminate harvested crop, nor be allowed to proliferate to the point that future weed control is difficult.

New technology allows infrared sensors to detect the difference between weeds and bare ground. Sensors tell the sprayer to apply only to the weeds and not to the bare ground. This technology is not yet sufficiently tested in vineyards.

### VI. PEST MANAGEMENT

Managing insect and disease pests is one of the key tasks of any vineyard manager and involves numerous decisions throughout the growing season. Effective management involves monitoring weather conditions, correctly identifying insects and disease pathogens present in a vineyard, taking account of differences in varietal susceptibility to diseases, and choosing appropriate control methods, including pesticides. Collective use of these multiple tactics for making informed decisions forms the basis for Integrated Pest Management (IPM) programs that effectively and economically control pests while minimizing environmental risk.

This section emphasizes correct pest identification, use of scouting and treatment thresholds for insect pests, phenology (vine development)-based disease management, integration of canopy management into disease management, resistance management and improved sprayer technology to protect vines from pests.

| What type of canopy<br>sprayer is used? | Application equipment is<br>used that increases target<br>deposition (i.e. reduces<br>drift) and allows for a<br>reduction in the amount<br>and/or rate of pesticides<br>used [e.g. a) recycling<br>sprayer, b) tower sprayer, c)<br>directed deposition sprayer]. | Application equipment is<br>used that improves<br>deposition and reduces drift<br>[e.g. a) airblast sprayer with<br>low drift nozzles such as air<br>induction nozzles, b)<br>modified airblast sprayer<br>with deflectors, c) nozzle<br>orientation adjusted to<br>improve deposition]. |   | The application<br>equipment does not<br>address drift (e.g. an<br>unmodified airblast<br>sprayer). |           |  |  |  |

The NY and PA Pest Management Guidelines for Grapes (http://ipmguidelines.org/grapes) provides an overview of spray drift management and nozzle types, including air induction nozzles. Air induction nozzles are well proven with herbicide applications and are recommended. Canopy application trials have been successful but further season-long trials are still needed.

Top and bottom deflectors should be fitted to airblast sprayers to funnel the pesticide-laden air into the canopy. Correct nozzle orientation (to overcome the effects of the uneven airblast resulting from fan rotation) allows the spray plume to target the canopy.

Dr. Andrew Landers notes that for nozzles < 150 microns in size, droplets are likely to drift, and if temperature is high and humidity low, droplets will evaporate. All nozzles can be purchased with different spray classification characteristics from "fine" to "coarse". These classifications appear in nozzle catalogs and will soon appear on pesticide labels. If nozzle output exceeds manufacturer recommendations by >10%, the nozzles need replacing.

The annual New York and Pennsylvania Pest Management Guidelines for Grapes (http://ipmguidelines.org/grapes) provides a pre-season checklist for sprayers, as well as a routine maintenance checklist.

Additional comments from Dr. Andrew Landers: Tractor speed should be fast enough to provide a good output per hour while ensuring canopy penetration; speeds too fast result in poor penetration in a full canopy, and moving too slowly results in poor output per day. Growers should also minimize the volume of air displaced by their sprayer, if possible. The airflow should be adequate to displace the air in the canopy with pesticide-laden air from the sprayer. The volume of spray should provide acceptable coverage, though the grower should not spray to the point where the leaves are dripping. Grower should apply sufficient spray for the developing canopy as the season progresses. Alternative row spraying (a common early season practice with airblast sprayers) provides inadequate coverage in many instances, and where disease pressure is highest, research has shown that spraying every row is preferable.

According to Dr. Wayne Wilcox (Dept. of Plant Pathology, NYSAES, Geneva), Eutypa canker has long been known as a cause of declining grapevines. More recently, vine decline has been recognized as a disease complex associated with a number of potential trunk-infecting fungi. Eutypa and some other fungi typically infect through pruning wounds, and then cause cankers that slowly expand down and around the infected arm, cordon, or trunk. A cross section through such cankers typically reveals a distinctive wedge-shaped zone of dead wood radiating from the center of the cylinder. Another group of vine-decline fungi do not cause such cankers. Rather, cross sections through trunks of symptomatic vines often display black spotting or gumming whereas longitudinal sections reveal black streaks through the water-conducting vessels of the wood. Current research suggests that decline symptoms from these infections are unlikely to occur unless the vines are subjected to stress. Therefore, viticultural practices designed to minimize vine stress should help to prevent/minimize the occurrence of such forms of vine decline. These practices would include timely irrigation, balanced nutrition, minimized trunk injury from machine implements and so forth.

Vines<br>rendered unproductive by<br>crown gall are either<br>removed or a new trunk is<br>trained up.<br><b>AND</b><br>Preparations designed to<br>rid the vine of crown gall<br>are NOT used as efficacy<br>has been poor in both |   | The Vineyard Manager<br>either cannot identify the<br>presence of crown gall, has<br>not addressed crown gall<br>problems in the vineyard,<br>or has addressed the<br>problems with topical<br>preparations that have<br>been proven to have poor<br>efficacy in both research<br>and grower trials. |           |  |  |
|  |  |   |   |  |           |  |  |

Crown Gall is a bacterial disease of grapevines that results in tumorigenic growth on trunks. According to Dr. Tom Burr (Dept. of Plant Pathology, NYSAES, Geneva) scion and rootstocks differ in their susceptibility to crown gall. In addition, the younger the vine is at infection, the greater the impact on the vine. Crown gall compromises the wound healing process by preventing normal differentiation of cells that are generated in the cambial zone following wounding.

| Are dormant fungicide<br>sprays applied?<br>[Note – dormant and post-<br>harvest are two distinct<br>time periods. Dormant<br>refers to the absence of<br>green tissue and leaves.] | Due to data indicating<br>marginal benefits and high<br>costs, dormant sprays are<br>NOT routinely applied to<br>the vineyard. |   | A single dormant spray<br>is applied. | Two or more dormant<br>sprays are applied to vines<br>with the general goal of<br>reducing overwintering<br>inoculum of powdery<br>mildew or Phomopsis. |           |  |  |  |

According to Dr. Wayne Wilcox, a single dormant spray MAY be appropriate if extreme levels of powdery mildew or Phomopsis are present on canes, but only if spray coverage is maximized with an efficient sprayer. Any benefits derived from such a spray are highly unlikely if a low efficiency sprayer, such as an unmodified airblast sprayer, is used.

Experiments conducted in upstate NY in the 1980s showed that dormant application of lime sulfur reduced the viability of overwintering inoculum of the powdery mildew and Phomopsis fungi, and sometimes improved the efficacy of the standard spray program that followed. However, these trials were conducted using a rate of over 30 gal/acre of lime sulfur in 300 gal/acre of water. (Note that lime sulfur is not a mix of lime + sulfur but rather calcium polysulfide, a completely different material.) This rate is extremely expensive and impractical. Lower rates (e.g. 10-12 gal lime sulfur in 100 gal water per acre) have been advocated in California, but data on their efficacy is very limited. In a recent NY trial, they provided only modest benefits at a relatively high cost. Most conventional fungicides should have little or no activity if applied during the dormant season, nor are they labeled for use at that time of year.

|                     |                                 |                            |                          |                        |           |
|                     |                                 |                            |                          |                        |           |

Overwintering inoculum of black rot and Phomopsis should be minimized by pruning and disposing of infected canes and bunches during the dormant season. Fungicide sprays should include a minimum of an immediate pre-bloom application and a post-bloom application 10-14 days later with materials providing protection against all four diseases. For varieties (e.g. Niagara) and locations subject to severe Phomopsis infections, an effective material is often required soon after cluster emergence as well. The need for additional applications (either pre- or post-bloom) are determined each year depending on weather conditions, over-wintered inoculum potential, and the presence of current-season infections as determined by scouting.

| Is scouting done for<br>fungal and viral<br>diseases? | Scouting is done every<br>other week or at key<br>phenological times<br>preferably by the same<br>person. Scouting results<br>are recorded and entered<br>into a historical database.<br>Vines are scouted May<br>through September. | Scouting is done<br>occasionally, often targeting<br>hot spots. Records of<br>scouting results are kept<br>and entered into a historical<br>database. | Scouting is done<br>informally (e.g. tractor<br>scouting) or on an<br>irregular basis. No<br>records are kept. | Scouting is not done. |           |  |  |
|   |  |   |  |                       |           |  |  |

Monitoring of fungal and viral diseases requires vigilance. Particularly with fungal diseases, it is important to address any problems as soon as possible. Remedial steps tend to be much more effective in the early stages of infection vs. during a raging epidemic. Ideally, in a given vineyard block, 5% of the vines or a minimum of 10 vines are examined weekly for signs of disease. These vines can be chosen using historical records to ensure that hotspots are the first to be scouted. Other options are randomly chosen vines or vines that are permanently tagged. Permanent tags offer the additional advantage of charting a range of measurements (e.g. vine pruning weight, disease status, etc.) from year to year. Both foliage and fruit should be examined for signs of disease.

| Where possible, are<br>reduced risk fungicides,<br>biopesticides, minimum<br>risk fungicides and/or<br>organic fungicides used? | Where practical, these<br>materials are used for<br>control of fungal diseases<br>and total >50% of the spray<br>materials used. | These materials are used<br>for control of fungal<br>diseases and total at least<br>20% of the spray materials<br>used. | These materials are used once or twice. | These materials are never used. |           |  |  |

See **www.vinebalance.com** for a description of reduced risk, minimum risk, organic and bio-pesticides.

- For a complete list of minimum risk materials, go to: http://www.epa.gov/oppbppd1/biopesticides/regtools/25b\_lis t.htm
- For a complete list of bio-pesticide materials, go to: http://www.epa.gov/oppbppd1/biopesticides/index.htm

The OMRI list of certified organic materials can be accessed via the web at **www.omri.org**.

When choosing a spray material, consider both the potential efficacy against the target pest, as well as, other aspects of the compound. Copper compounds, for example, are effective downy mildew (and to a lesser extent, Phomopsis and black rot) materials that are allowed in organic programs. Unfortunately, in other grape growing regions worldwide, copper use has been banned (outright bans as well as bans in organic production exist) due to concerns about the accumulation of this heavy metal in soils. Thus in this particular circumstance, copper would be considered an organic option (the OMRI approved labels) but should be used sparingly and only when necessary.

## DISEASE MANAGEMENT

Additional comments from Dr. Wayne Wilcox: Reducing the application rates of fungicides can save money and reduce the potential for shortterm environmental pollution. However, this is not a long-term sustainable practice for certain fungicides. Specifically, reducing rates of the DMI fungicides (also called SIs or sterol inhibitors - Elite, Nova, Procure, and Rubigan) and the strobilurins (Abound, Flint, Sovran) is known to promote the development of resistance to these materials. In contrast, reducing the rates of traditional protectant materials (Dithane, Manex, Penncozeb, coppers, sulfurs, etc.) has no impact on resistance development but can shorten the duration of their active period. Also, note that pesticide rates are typically expressed on a per-acre basis for both legal purposes and convenience, although target organisms actually respond to a rate per unit area of canopy volume. Thus, a rate of 3 oz/acre applied to a thin canopy early in the season, may provide the same level of activity as 6 oz/acre applied to a thick canopy in mid-summer. In short, efforts to reduce pesticide rates should be governed not only by the particular materials in use but also by the canopy volume.

| Can the Vineyard<br>Manager identify<br>insect and mite<br>pests and the<br>damage they<br>cause? | The Vineyard Manager can<br>identify all of the following<br>insect/mite pests and the<br>damage they cause:<br>• Major Insects<br>• Minor Insects<br>• Mites<br>• Any unknown pest is ID'd<br>with outside help<br>• VM has knowledge of crop<br>susceptibility and insect life<br>cycles. | Using fact sheets and<br>websites, the Vineyard<br>Manager can identify a<br>majority of the insect and<br>mite pests, and the<br>damage they cause, and<br>has knowledge of crop<br>susceptibility and insect<br>life cycles. | The Vineyard Manager<br>has difficulty identifying<br>more than 3 insect and<br>mite pests and the<br>damage they cause. | The Vineyard Manager<br>cannot identify ANY<br>insect pests or the<br>damage they cause. |           |  |

Insects are found in regions noted – if no region is cited, insects are found in all regions:

Major Insects: Grape Leafhopper (FL), Potato Leafhopper (LI), Japanese Beetles, Grape Berry Moth, and Rose Chafer. Minor Insects: Cutworms, Flea Beetles, Thrips, Aphids, Girdlers, Gallmakers, Scale Insects, Grape Plume Moth, Grape Cane Borer, Banded Grape

Bug (FL & LE), Grape Rootworm (FL).

Mites: European Red Mite, Two Spotted Spider Mites.

Photos can be found at the following web address: http://www.nysipm.cornell.edu/factsheets. The following publications (see the reference section for details) also have good photos: Grape Pest Management, Compendium of Grape Diseases, and Grape IPM in the Northeast.

| Are dormant<br>miticide sprays<br>applied? | Due to the data indicating<br>marginal benefits, dormant<br>sprays are NOT applied to<br>the vineyard for mite<br>control. |   | A single dormant spray of a<br>labeled horticultural oil is<br>applied with the goal of<br>reducing the viability of<br>European Red Mite eggs. A<br>minimum of 100 GPA water is<br>used or amount of water as<br>per label directions. | More than one dormant<br>oil or other insecticide<br>spray is applied to vines,<br>all in accordance with<br>pesticide labels. |           |  |  |

Dormant oils, when applied properly, can provide some control of overwintering European Red Mites (ERM) in tree fruit, particularly apples. High water gallonage (200-300 gal/acre) and rates based on time of year/stage of growth are used. In apples, mites become progressively more susceptible to control with dormant oil as spring arrives.

Horticultural oil research has been conducted statewide. Sprays were applied at multiple timings with a backpack sprayer. Treatments were unsuccessful in controlling subsequent mite populations. Grower experience with airblast sprayers has been similarly disappointing. The location of mites in cracks and crevices and under bark makes control much more difficult than tree fruit. For areas with potentially high overwintering ERM populations, an efficient sprayer that achieves excellent coverage would be the best choice for dormant oil application. Coverage must be sufficient to penetrate areas where overwintering mites reside. Be sure to use an oil product labeled for dormant use in vineyards.

| Is spot treatment used<br>for insect/mite<br>infestations?  | If infestations are localized, only<br>the vineyard areas with<br>economically damaging levels of a<br>pest are treated. For example,<br>only the block by the wooded edge<br>is treated for berry moth; blocks A<br>& B but not C are treated for ERM. | Spot treatment is sometimes done.  |   | Spot treatment is never<br>done. If an insect or<br>mite outbreak occurs,<br>the entire vineyard is<br>treated. |           |  |
| Where practical, are<br>reduced risk,<br>minimum risk and/or<br>organic insecticides<br>and miticides or<br>biopesticides used? | These materials are always used for insect/mite control.  | Where effective and<br>economically feasible,<br>these materials are<br>used for insect and mite<br>control. |   | These materials have<br>not been used during<br>the growing season for<br>insect/mite control.                  |           |  |

See www.vinebalance.com for more information on reduced risk, minimum risk, organic and biopesticides. For a complete list of minimum risk materials, go to http://www.epa.gov/PR\_Notices/pr2000-6.pdf. For a complete list of biopesticide materials, go to http://www.epa.gov/pesticides/biopesticides/ingredients/index.htm.

The OMRI list of certified organic materials can be accessed via the web at **www.omri.org**.

When choosing a spray material, consider both the potential efficacy against the target pest as well as other aspects of the compound. Rotenone, for example, is an organically approved insecticide. It is also moderately toxic to ERM predators and highly toxic to fish, and in fact, it is used to remove unwanted fish populations. The economic sustainability of a low risk material must also be considered. It is not sustainable if it is a prohibitively expensive treatment, particularly one with marginal benefits in terms of pest control.

## VII. PESTICIDE MANAGEMENT

This section covers procedures for safe storage, mixing and loading, and handling of pesticides to protect worker health, and avoid the potential for contamination of wells, groundwater, and ponds.

Managing mixing and loading processes to protect health and contain or avoid spills is particularly important, since pesticides are most concentrated before they are mixed in the spray tank. Simple precautions described in this section can greatly reduce the risks to worker safety and reduce the potential for spills and groundwater contamination. Use of worker protection standards (WPS) to provide worker protective equipment, signage, and decontamination sites is mandated by the Environmental Protection Agency (EPA) and the Maryland Department of Agriculture. A synopsis of Maryland pesticide applicators laws and regulations can be obtained through the University of Maryland Extension Service.

Cost-sharing through local Soil and Water Conservation Districts for improving mixing, loading, and storage facilities has assisted growers in financing improvements in the past and may be available in the future.

Regulations concerning use of surface water (ponds) for filling sprayers vary. Long Island vineyards exclusively use wells or municipal water supplies. In other areas, growers commonly use water pumped from ponds, particularly where wells or municipal water supply are not available. When ponds are used as a source, the filling area should be below the grade of the pond, and at least 100 feet away from surface water. Nurse tanks are recommended, because they reduce the amount of time it takes to fill spray tanks.

An acceptable Reduced Pressure Zone (RPZ) device contains a minimum of two independently acting check valves with an automatically operated pressure differential relief valve between the two check valves.

## VIII. CONTINUING EDUCATION

Vineyard management practices are constantly changing. New techniques, crop protection materials, and research results can and should influence your practices. Continuing education is important, because it facilitates the flow of research-based information, allows for exchange of ideas among growers, and helps growers understand how agricultural practices influence the environment and their community.

This section addresses what information sources, references, and educational venues growers can use to keep up to date with new ideas and practices.

#### **ACTION PLANS**

Upon completion of the workbook, the next step is to develop an action plan based on the results of your self-assessment that will address the practices that you believe you can effectively modify within the financial and management capacity of your farm. Concentrate on the issues that you assessed as a "3" or "4", with the goal of reaching the more sustainable "1" or "2" rating for that practice. If there are practices that you assessed a "2" that you feel you can easily climb to a "1", include those as well. The action plan is yours, and only you will know what is practical and possible on your farm.

Below you will find an Action Plan Template that includes an example of a practice to be modified. All of the practices that you assessed a "3" or "4" should be listed on the template. For each potential action in your action plan, you must (1) decide if you want to take action on that specific practice (Action Y/N), (2) determine what you want to do in regard to that action (Goals), (3) organize your steps along the road to adoption of the modified practice (Action Steps), and (4) provide a timeline for completion (Timetable). The template also contains space for the completion dates of your action steps as well as space for any pertinent notes regarding your proposed action. It is important that your action plan details all of this information in order to fulfill the requirements for potential cost-sharing opportunities with your Soil and Water Conservation District (SWCD) and Natural Resources Conservation Service (NRCS) offices. The second page of the action plan template is left blank and can be photocopied as necessary to include all of the practices that you assessed a "3" or "4".

Extension personnel from your regional grape program will provide as much assistance as you desire. In addition, your local Soil and Water Conservation District office is equipped to aid action plan development and educate you on possible cost-sharing opportunities for actions in your plan. After you have completed the workbook and are prepared to construct an action plan, contact your grape and Soil and Water Conservation District programs to take advantage of the guidance available to you.
